# Substituting T-braces for continuous lateral braces on wood truss webs 

By Cheryl Anderson,
Frank Woeste, PE, and Donald Bender, PE

## Introduction

Web bracing in trusses is essential for several reasons. With one lateral brace, a compression member is able to carry up to four times the normal load; when two lateral braces are used, the member may carry a load up to nine times more. Lateral braces resist lateral deflection in the webs and decrease the effective buckling length of the web members (Underwood et al., 2001).

T-braces increase the effective stiffness of webs - allowing higher compressive design loads (Shrestha et al., 2001).

Truss webs are assumed to be loaded axially - either in compression or tension. When the design compression load exceeds the unbraced web capacity, the truss designer can specify a lateral brace at the center of the web to increase the design load capacity. In some cases, two braces are needed at the third points to further increase the load capacity of the web. Compression members with an $\mathrm{L} / \mathrm{d}$ greater than 50 and tension members with an $\mathrm{L} / \mathrm{d}$ greater than 80 require lateral bracing regardless of the load level in the web (Truss Plate Institute, 1995). The truss designer typically notes the need for permanent bracing on the truss design drawing by placing a small rectangle on the web (See Figure 3, for

Figure 1. Elements of continuous lateral bracing for webs in a roof system.

Figure 2. Correct installation of a $2 \times 4 \mathrm{~T}$-brace on a web as assumed in the development of Tables $1 \mathrm{a}, 1 \mathrm{~b}, 1 \mathrm{c}$, and 1 d .
example, where bracing is required on webs B-K, C-J, E-J and F-I). The contractor has two options for bracing webs when required-either Continuous Lateral Braces (CLBs) or T-braces.

The first option, when using CLBs, is a piece of lumber that extends through several trusses, attached to a web member at the center, or two pieces attached at the $1 / 3$ points. Figure 1 shows how the CLB is placed into the roof system and the diagonal bracing that is also required. CLBs are commonly used in construction, especially with trusses spaced 2-ft. on-center.

For trusses with a $4-\mathrm{ft}$. to $10-\mathrm{ft}$. spacing, a T-brace approach may be a more practical option, requiring less lumber than a CLB system. T-braces can be installed on the ground, eliminating a fall hazard, and no web diagonal bracing is needed when the truss is installed in the roof. A T-brace, as defined by this paper, is a $2 \times 4$ piece of stress-rated-lumber that is attached symmetrically to the narrow edge of the compression web member as shown in Figure 2. The T-braces tested and used in this paper to create design tables extend within to six inches from either end of the web. The minimum allowable nail size required is 16 d Box $(0.135$ in x 3.5 in ) nails, placed at 6 inches on center with the first nail 3 inches from the end (Shrestha et al., 2001).

## Design Procedure

T
he procedure used to reach the allowable load values presented in Tables $1 \mathrm{a}, 1 \mathrm{~b}, 1 \mathrm{c}$, and 1 d is from the National Design Specification (NDS) for Wood Construction (AF\&PA, 1997). The allowable load is found using the tabulated allowable compression parallel to grain,

Figure 3. Example truss design drawing showing web forces.
appropriate adjustment factors, and properties of the lumber.

Design criterion for a compression member is:
$f_{c} \leq F_{c}{ }^{\prime}$
where:
$\mathrm{f}_{\mathrm{C}}=P / A_{W}=$ compression stress parallel to grain, psi,
$\mathrm{F}_{\mathrm{C}}{ }^{\prime}=$ Adjusted allowable compression stress parallel-to-grain, psi,
$P=$ Allowable load in the web, lbs., and,
$A_{w,}=$ Cross-sectional area of the web, in. ${ }^{2}$.

The allowable load in a web with a specific length is:
$P=A_{W}{ }^{F} C C_{D} C_{P} C_{M} C_{t} C_{i}$
where:
$\mathrm{F}_{\mathrm{C}}=$ tabulated allowable compression stress parallel-to-grain, psi,
$C_{D}=$ load duration factor,
$C_{p}=$ column stability factor,
$C_{F}=$ size factor for sawn lumber,
$C_{M}=$ wet service factor,
$C_{t}=$ temperature factor, and
$C_{i}=$ incising factor.
As stated before, the $\mathrm{F}_{\mathrm{c}}$ values are tabulated in the NDS. The load duration factor for a snow plus dead load combination is 1.15 . The size factor is 1.0 for Southern Pine; for other species, the size factor is tabulated in the NDS Supplement.

The column stability factor is given by:

$$
\mathrm{C}_{\mathrm{p}}=\frac{1+\left(F_{c E} / F_{c}^{\prime}\right)}{2 c} \sqrt{\left[\frac{1+\left(F_{c E} / F_{c}^{\prime}\right)}{2 c}\right]^{2}-\frac{\left(F_{o E} / F_{c}^{\prime}\right)}{c}}
$$

$\mathrm{c}=0.8$ for sawn lumber
$F_{C}=F_{C} C_{D} C_{F}$
$\mathrm{F}_{\mathrm{CE}}=K_{C E} E_{T} /\left(L_{e} / d\right)^{2}$
KCE $=0.3$ for visually graded lumber, 0.418 for machine stress rated lumber.
$\mathrm{E}^{\prime} \mathrm{T}=$ modified modulus of elasticity of T-braced web, as determined by Equation 4 (Shrestha et al., 2001), psi
$\mathrm{L}_{\mathrm{e}}=$ effective length of the web, in
$L_{e}=L_{W} K_{e}$
$\mathrm{K}_{\mathrm{e}}=$ buckling length coefficient
$L_{W}=$ unbraced web length, in
$d=$ least dimension of web member, typically equal 1.5 in .

A buckling length coefficient of $\mathrm{K}_{\mathrm{e}}$ $=0.8$ has been commonly used in truss design and was proven to be accurate in laboratory tests (Grant et al., 1986).

A regression equation was proposed by Shrestha et al. (2001) to determine the stiffness of a web with a T-brace attached. In this paper, the format of the equation is slightly modified:

Figure 4. Truss used to determine unknown web lengths.

## Design Examples

1. How to find the web load on a truss design drawing:

The web load will be indicated on a truss drawing as a force in pounds and identified with the web end points. If the web is in compression, the force will either be negative or labeled with a "C". In Figure 3, the force in member B-K is $-2,578$ lbs., so it is in compression.
2. How to determine web length:

If requested, truss manufacturers could print the web length directly on the truss design drawing. When the length is not specified, use the following steps and Figure 4 to estimate it:
i. Find points $\mathrm{X} 1, \mathrm{X} 2, \mathrm{Y} 1$ and Y 2 on the truss drawing. X 1 and X 2 can be read directly from the drawing or requested from the truss designer. In the example, $\mathrm{X} 1=16 \mathrm{ft}$. (192 in.) and
$\mathrm{X} 2=13 \mathrm{ft} .-4 \mathrm{in}$. (160 in.).
ii. Length Y2 can be calculated using X 2 and the roof slope: $\mathrm{Y} 2=\mathrm{X} 2 *$ (slope). Y2 in the example is $160^{*}(4 / 12)=53.3 \mathrm{in}$. In a typical post frame truss with a flat bottom, Y1 would equal 0 .
iii. Use the following equation to find the length of the web, $\mathrm{L}_{\mathrm{W}}$ :

$$
L_{w}=\sqrt{(X 1-X 2)^{2}+(Y 2-Y 1)^{2}}
$$

Substituting the numbers from the example into the equation,

$$
L_{w}=\sqrt{(192-160)^{2}+(53.3-0)^{2}}
$$

$L_{W}=62.6$ in. Round to the nearest web length that produces the lower allowable compression load in the applicable table based on web grade and species grouping.

For a T-brace to work, there are specific requirements that must be met. First, LW must be less than 14 ft ( 168 in.) to meet NDS slenderness restrictions of $\mathrm{L}_{\mathrm{e}} / \mathrm{r}<173$ (Shrestha et al., 2001). Secondly, the formulas used in this paper are only valid for the web lengths shown in the tables, $2 \times 4$ webs and $2 \times 4$ stress rated T-braces. The design data presented do not apply to $1 \times 4$ braces or a nailing schedule other than tested. A closer nail spacing and longer or larger diameter nails are permitted provided they do not split the lumber.

## 3. One CLB

In Figure 3, the truss design drawing calls for a single CLB on member B-K (and F-I). From the drawing, the load in this web is $-2,578 \mathrm{lbs}$., which means it is in compression. The webs are $2 \times 4$ No. 2 Southern Pine and the

Table 1a
Allowable compression load for a $2 \times 4$ No. 3 or Stud grade Southern Pine1,2 web of a specific length having a $2 \times 4$ T-brace with $E$ value as shown.

Truss web

| 132 | 2070 | 2130 | 2190 | 2260 | 2320 | 2380 | 2450 | 2510 |
| 144 | 1740 | 1790 | 1840 | 1900 | 1950 | 2000 | 2060 | 2110 |

${ }^{1}$ Except for Southern Pine, tabulated values are conservative for other $2 \times 4$ grades and species groupings that have $F_{C}$ values equal to at least 775 psi and E values equal to at least 1.4 million psi.

2 For $2 \times 4$ T-brace extending to within six inches of web member ends, attached by 16 d Box nails ( $0.135 \mathrm{in} \times 3.5 \mathrm{in}$ ) and placed at 6 inches on center starting at 3 inches from the brace ends.
desired T-braces are $2 \times 4$ Stud Spruce-Pine-Fir (SPF). From Table 2, the E is 1.2 million psi for Stud grade SPF. By following the method described above, the calculated web length was 91.2 in . Use Table 1 b because the webs are made from No. 2 Southern Pine. Round 91.2 in. up to 92 in. since the table value is less for 92 in. compared to 90 in. From the column labeled $\mathrm{E}=1.2$ million psi and the row labeled 92 in., the allowable load in the web is $4,360 \mathrm{lbs}$. A SPF T-brace is adequate on web $\mathrm{B}-\mathrm{K}$ (and $\mathrm{F}-\mathrm{I}$ ) in place of a CLB.
4. Two CLBs

Also in Figure 3, two CLBs are shown on member C-J (and E-J). The load in this member is $-4,126 \mathrm{lbs}$. The webs are 2 x 4 No. 2 Southern Pine and the T-braces that we would like to use again are $2 \times 4$ Stud SPF ( $\mathrm{E}=1.2$ million psi ). The calculated web length was 100 in . Reading from Table 1b, the maximum load that this web could carry with a T-brace is $3,890 \mathrm{lbs}$. Using a Stud SPF T-brace on member C-J instead of a CLB would not be adequate because $3,890 \mathrm{lbs}$. is less than $4,126 \mathrm{lbs}$. However, from Table 1 b , using a T-brace with an E of 1.5 million psi would produce an allowable web load greater than the $4,126 \mathrm{lbs}$. required.

Table 1d
Allowable compression load for a $2 \times 4$ Stud grade Spruce-Pine-Fir 1,2 web of a specific length having a $2 \times 4$ T-brace with E value as shown.
Truss web

| Truss web <br> length (in.) | 0.9 | 1 | 1.1 | 1.2 | 1.3 | 1.4 | 1.5 | 1.6 |

${ }^{1}$ Except for Southern Pine, tabulated values are conservative for other $2 \times 4$ grades and species groupings that have Fc values equal to at least 725 psi and E values equal to at least 1.2 million psi.

2 For $2 \times 4$ T-brace extending to within six inches of web member ends, attached by 16 d Box nails ( $0.135 \mathrm{in} \times 3.5 \mathrm{in}$ ) and placed at 6 inches on center starting at 3 inches from the brace ends.

## Discussion

Using higher grades of web material or using larger webs ( $2 \times 6$ or $2 \times 8$ ) are possible ways to eliminate or reduce the amount of CLBs needed. For example, a $2 \times 6$ web will carry about 50 percent more load than a $2 \times 4$ of the same grade and species, possibly reducing the need for a CLB. The value of using a higher grade of $2 \times 4$ web lumber varies with the web length. For short webs, a No. 2 Southern Pine (SP) web will carry up to 69 percent more load

## Table 2

Typical $2 \times 4$ lumber grades and species groupings that may be used as T-braces.
$2 \times 4$ Grade and Species Groupings*E, million psi
Stud or No. 3 Western Woods0. 9
Stud or No. 3 Spruce-Pine-Fir (South) 1.0
Stud or No. 3 Douglas Fir-South 1.1
Stud or No. 3 Hem FirStud or No. 3 Spruce-Pine Fir 1.2
No. 1 Douglas Fir-South or No. 2 Hem-Fir 1.3
Stud or No. 3 Douglas Fir-LarchStud or No. 3 Douglas Fir-Larch (North)No. 2 Non-Dense, No. 3, or Stud Southern Pine 1.4
No. 1 or No. 1 \& Better Hem-Fir, or 1650f-1.5E MSR 1.5
No. 2 or No. 1 Non-Dense Southern PineNo. 2 Douglas Fir-Larch 1.6
*The NDS (1997) Supplement contains a complete list of species and tabulated E values for consideration by the bracing designer.
than a Stud or No. 3 SP web. For very long webs, a No. 2 SP web will carry about 14 percent more load than a Stud or No. 3 SP web.

The load carrying capacity of T-braced SP webs of No. 3 and No. 2 grade can readily be seen by inspection of Tables 1 a and lb , respectively. For example, assuming a T-brace with an E of 1.2 million psi and LW equal 60 in., the No. 2 web will carry 56 percent ( $6460 / 4140$ ) more load than a No. 3 or Stud grade web. It may be a good practice to use a minimum of No. 2 SP webs in long span post-frame trusses to minimize the number of CLBs specified on the truss design drawing, and when a CLB is noted on the truss design drawing, a T-brace is more likely to substitute for the CLB.

## Conclusion

he T-brace design tables provided in this paper show the allowable load that can be applied to a $2 \times 4$ truss web with a $2 \times 4$ T-brace. When a CLB is required on a web, a $2 \times 4$ T-brace may be substituted only if the web load is lower than the tabulated value for the web grade and species, web length, and T-brace E. T-braces are recommended when the trusses are 4 to 10 ft . on center because they can be installed on the ground before the trusses are lifted onto the roof. Also, by using T-braces on the webs instead of CLBs, it is likely that less lumber and labor will be required to erect the trusses and install permanent web bracing. The methods used in this paper were developed specifically for selected $2 \times 4$ webs braced with a $2 \times 4$ and installed as depicted in Figure 2.

$L_{e}=K_{e} L_{W}=0.8 * 54 \mathrm{in} .=43.2 \mathrm{in}$.
$\mathrm{L}_{\mathrm{e}} / \mathrm{d}=43.2 / 1.5=28.8$
$\mathrm{F}_{\mathrm{C}} \mathrm{E}=\mathrm{K}_{\mathrm{CE}} \mathrm{E}^{\prime} /\left(\mathrm{L}_{\mathrm{e}} / \mathrm{d}\right)^{2}=0.3 * 3.21 \times 10^{6} /(28.8) 2=1,161 \mathrm{psi}$
$F_{C}{ }^{*}=F_{C} C_{D}=975 * 1.15=1,121$. psi (Snow plus dead load assumed.)

Note: For other than Southern Pine, add CF to Fc* calculation.
$F_{C E} F_{C_{C}}{ }^{\star}=1161 / 1121=1.036$
$\mathrm{C}=0.8$
$C_{n}=(1+1.036) / 1.6-\left\{((1+1.036) / 1.6)^{2}\right.$
$\mathrm{C}_{\mathrm{p}}=\frac{1+\left(F_{c E} / F_{c}^{*}\right)}{2 c} \sqrt{\left[\frac{1+\left(F_{c E} / F_{c}^{*}\right)}{2 c}\right]^{2}-\frac{\left(F_{c E} / F_{c}^{*}\right)}{c}}$
$-1.036 / 0.8\}^{1 / 2}=0.703$
$F_{C}{ }^{\prime}=F_{C} C_{D} C_{p}=975 * 1.15 * 0.703=788$. psi
$P_{\text {allowable }}=F_{C}^{\prime} A=788^{*}(1.5 * 3.5)$
$=4,137$. lbs.
A note on Load Values in Tables 1a-1d.
In Tables 1a, 1b, 1c, and 1d, the allowable value of P increases with web lengths up to a point and then it decreases slightly. This result is contrary to the typical column relationship whereby the allowable load is inversely related to the effective length of the column. For example, for the case of a 0.9 million psi T-brace in Table 1a, the unusual behavior stems from the equation for $\mathrm{F}_{\mathrm{CE}}$, which increases in value up to $L_{W}$ equal 62 in. The allowable load, $P$, is dependent on the Column Stability Factor, $C_{p}$, which is dependant on $F_{C E}$. In this particular application of a T-braced web, $\mathrm{F}_{\mathrm{CE}}$ is adversely affected by $L_{W}$ in the usual manner, but positively affected by $E_{T}$ because $E_{T}$ is a linear function of $R$. $R$ equals ( $L_{W}-12$ )/ ${ }^{L_{W}}$ and increases with $L_{W}$ up to a constant value of $8 / 9$. When $L_{W}$ is greater than 62 in . for the example case, $\mathrm{F}_{\mathrm{CE}}$ begins to decrease, so both $C_{p}$ and the allowable load decrease.
